

Intersectional Analysis of School Violence: How Race and Gender Compound Campus Risks

Research Question: Does the intersection of marginalized race and gender identities create a non-linear compounding premium on school violence and physical victimization?

1 Study Framework

Group Definition

- Baseline (0,0): Majority Cis-Hetero (Reference group)
- Proxies (1,0 / 0,1): Majority LGBTQ+ Proxy | Minority Cis-Hetero
- Intersectional (1,1): Minority LGBTQ+ (Compound risk group)

Response Variables

- Subjective Fear: School_Safety_Index (Psychological anxiety & truancy)
- Objective Injury: Weapon_Threat_Index (Weapon threats & physical trauma)

2 Statistical Method

Method: Ordinary Least Squares (OLS) Linear Regression with Explicit Interaction Terms ($Is_Minority_Race * Is_Female$).

Assumption Check: Robustly passed the large-sample asymptotic condition ($n = 13,019$). Central Limit Theorem allows OLS models to maintain high asymptotic variance efficiency even under heavily skewed distributions.

3 Key Result

TOTAL SAMPLE
13,019

INTERACTION SIGNIFICANCE
 $p < 0.05$

RISK AMPLIFICATION
2.5 x Higher

4 Conclusion

1. Beyond Additive Risks

Campus violence does not operate through simple additive demographic risks. Evaluating race or sexual orientation in isolation completely misses the severe systemic hazards concentrated at their intersection.

2. The Intersectional Divergence

A profound divergence exists between psychological fear and physical danger. While subjective fear is elevated across all minoritized groups, objective weapon injuries exhibit a drastic, non-linear spike exclusive to intersectional youth.

3. Mathematically Proven Premium

The OLS interaction term ($Is_Minority_Race * Is_Female$) yields a statistically significant coefficient ($p < 0.05$). This mathematically confirms that compound marginalization acts as a risk multiplier.

[Subjective Fear Profile: Race Predominates]

[Objective Physical Injury: Sexual Identity Spikes]
